

4th class–

1- How python works:

i- Compilation process:

While running a Python script (.py), the Python compiler first checks your code for syntax errors. If the code is valid, it translates the source code into an intermediate format called Bytecode.

i-What is Bytecode: It is a low-level, platform-independent set of instructions. It isn't machine code that CPU understands. Only Pvm only understand bycode instructions. it is specific to Python.

ii-It is often stored in a folder named `__pycache__` with a .pyc extension.

ii. Interpretation

The Bytecode is then sent to the Python Virtual Machine (PVM). The PVM contains the Interpreter,

i-The Interpreter reads the Bytecode line-by-line.

ii-It converts each line into Machine Code (binary 0s and 1s) that your specific computer hardware can execute.

2. Compiler

What it does: It translates the entire source code into machine code all at once before the program runs.

3. Interpreter

What it does: It translates and executes the code line-by-line during runtime.

–5th class–

1. Data Types in Python

Data types 5 types such as:

- Int: numbers (e.g., 10, -5).
 - Float: Decimal numbers (e.g., 10.5, 3.14).
 - String: in quotes (e.g., "Hello").
 - bool: either True or False.
 - None: It indicates that a variable exists but doesn't have a value yet.
-

2. Operators in Python

- + (Addition), - (Subtraction), * (Multiplication), / (Division)
- // (Floor Division): Returns the whole number after division (e.g., $7 // 2 = 3$).
- % (Modulus): Returns the remainder (e.g., $7 \% 2 = 1$).
- (Exponent): Power (e.g., $2^3 = 8$).

Another Comparison Operators

- == (Equal), != (Not Equal)
- > (Greater than), < (Less than)
- >= (Greater than or equal), <= (Less than or equal)

C. Logical Operators

- and: Returns True if both statements are true.
- or: Returns True if one statement is true.
- not: Reverses the result (e.g., not (True) is False)

D. Assignment Operators

Used to assign values to variables.

- = (Assignment), += (Add and assign), -= (Subtract and assign).

----6th class---

1. Input & Type Conversion

By default, the `input()` function always takes data as a String.

- Concatenation: Using `+` with inputs will join them as text (e.g., `"10" + "20"` results in `"1020"`).
- Type Casting: To perform math, need to convert the string to an integer using `int()`.
 - *Example:* `result = int(first) + int(second)`

2. String Formatting Approaches

several ways to combine strings and variables:

- f-strings : The most modern and readable way.
 - *Syntax:* `f"Hello {name}"`
- `.join()` Method: *Syntax:* `" ".join([first_name, last_name])`
- `.format()` Method: Uses placeholders `{}` to insert values.
 - *Syntax:* `"{} {}".format(a, b)`, if i extend 1 variable, then will be needed `{}` more extra one.
- String Multiplication: Make repetition a string multiple times using `*`.
 - *Example:* `"sorry " * 1000`

3. Useful String Methods

Python built-in functions:

- `.upper()` / `.lower()`: Converts text to all capital or all small letters.
- `.title()`: Capitalizes the first letter of every word.
- `.capitalize()`: Capitalizes only the very first letter of the string.
- `.swapcase()`: Flips cases (Lower to right , Upper to Lower).
- `.count("x")`: Counts how many times a specific character appears.
- `.find("word")`: Returns the index (position) of the first occurrence of a word.

4. Variable Overriding

In Python, variables are dynamic. If i assign a new value to an existing variable name, the old value is replaced (overridden).

- *Example:* If `number = 10` and then `number = 30`, the final value stored is 30.

—7th Class—

Python String Methods and Operations

1. Fundamental String Operations

Python strings are indexed sequences of characters where indexing starts at 0 and negative indexing starts from the end at -1.

Operation	Description	Example (x = "hello world")
len(x)	Returns the total number of characters in the string.	11
Indexing [i]	Accesses a character at a specific position.	x[4] → 'o'
Negative Indexing [-i]	Accesses characters starting from the end.	x[-1] → 'd'

String Slicing

i-x[0:5] / x[:5]: Extracts characters from index 0 up to (but not including) index 5 (example: "hello").

ii-x[6:]: Extracts characters from index 6 to the very end (example:"world").

2.String Modification Methods

1-.replace(): Replaces a specific part of the string with new text.

- `"rocky".replace("r", "p")` → output: `'pocky'`

2-.strip(): Removes extra spaces from both the start and the end.

- `" hello ".strip()` → output: `'hello'`

3.lstrip(): Removes spaces only from the left side.

- `" hello ".lstrip()` → output: `'hello '`

4.rstrip(): Removes spaces only from the right side.

- `" hello ".rstrip()` → output: `' hello'`

5.upper(): Converts all letters to uppercase.

- `"python".upper()` → output: `'PYTHON'`

6.lower(): Converts all letters to lowercase.

- `"PYTHON".lower()` → output: `'python'`

7.title(): Capitalizes the first letter of every word.

- `"hello world".title()` → output: `'Hello World'`

8.split(): Splits the string into a list based on a separator.

- `"a,b,c".split(",")` → output: `['a', 'b', 'c']`

9.capitalize(): Capitalizes only the first letter of the entire string.

- `"hello".capitalize()` → output: `'Hello'`

Methods:

1-.startswith(): Checks if the string starts with a specific value.

- `"apple".startswith("a")` → output: True

2-.endswith(): Checks if the string ends with a specific value.

- `"apple".endswith("e")` → output: True

3-.find(): Returns the index position of the first occurrence of a value.

- `"hello".find("e")` → output: 1

4-.count(): Counts how many times a value appears in the string.

- `"banana".count("a")` → output: 3

5-.isdigit(): Checks if all characters in the string are numbers.

- `"123".isdigit()` → output: True

6-.isalpha(): Checks if all characters in the string are letters.

- `"hello".isalpha()` → output: True

4. String Validation

Basically, return True or False.

- `.isalpha()`: True if all characters are alphabetic (A-Z).
- `.isdigit()`: True if all characters are digits (0-9).

- `.isalnum()`: True if all characters are alphanumeric (letters or numbers).
- `.isspace()`: True if the string consists only of whitespace.
- `.istitle()`: True if the string follows title case rules.
- `.islower()`: True if all characters are lowercase.

5. Input and Output Formatting

User Input

```
1-name = input("Enter your name: ")
```

```
2-age = int(input("Enter your age: "))
```

Printing Techniques

1. Standard Print: `print("Name:", name, "Age:", age)` or,
2. F-String: `print(f"Your name is {name} and your age is {age}")`.

—8th Class—

if Statement: Executes the code block only if the condition is **True**.

- `if age >= 18:` → **Result:** Checks if age is 18 or more.

elif (else if): Used to check multiple conditions one after another if the previous ones were False.

- `elif score >= 80:` → **Result:** Checks this only if the first `if` failed.

else: Executes only if none of the above conditions are met.

- `else :` → **Result:** The final option and if any of the condition fail then else condition will work

—9th class—

The Python ternary operator evaluates a condition and returns a specific value in a single line

Ternary operator = [Value_If_True] if [Condition] else [Value_If_False].

```
status = "Pass" if marks >= 40 else "Fail"
```

i-**Logic:** If marks are 40 or more, status is "Pass"; otherwise, it is "Fail".

ii-**Output:** "Pass" (if marks = 50)

10 th 11 th no class

python data types - int, string, float (decimal), bool (yes/no), None (no value).

7620

input () gives a string for value γ_1 , γ_2 of this type (string & γ_1 value
int, float (32 bit) will find out what is the name = int (input your name)

'full_name' = first_name + " " + last_name.

6112502 first_name = "R"

last-name, "H."

Print (" ".join

FN

Docstring = multiline comment.

Alphabetic (A-z; a-z.).

Numerical (0-9 any digit).

Alphanumeric (A-Z, a-z, 0-9).

Strip() = left, right space remove

$L_n(\cdot) = \text{left}$ " " , Right space - Rstep

isalpha = only alphabet character (space, digit, etc.)

is digit, • isalnum = (A, a, 0-9) কিন্তু space বাক্যমণি নয় না।

as space (concat string empty after check) text = " "

data type check = type(3) // Number, type("Rocky") // string

11 $\rightarrow$ datatype $\rightarrow$ `list("rock") = 0/p = "r", "o", "c", "k" // single string list`
`list("rock", 12, 3.14, true)` $\rightarrow$ list of 4 elements, first element is a string, second is an integer, third is a float, fourth is a boolean.

List - mutable - get ordered way (for array) [Int, String, Bool, Obj, List]

↳ duplicate allow ∞ , zero indexed heterogeneous types allow (tagged mix data types)

* Siddik = [] - empty list // faster // better lexical syntax.

Sidelik = list() → empty list → constructor syntaxon. // Get usage - w/ ty data

type of list is converted into list() using

Ex: `chars = list('Hello') // list` convert 26bit - output - 'H', 'e', 'l', 'l', 'o'

```
mixed = [42, 'Hello', 3.14, True] // O/P 3642 [42, 'Hello', 3.14, True]
```

- append method - it only list add ∞ times, list extend ∞ times unlimited

insert (1, "Lychee") // 12, index 9 add(insertion) 2, 8

remove, delete, pop(variable with in pop value return 0) $\rightarrow$ pop remove + return 0

List 2 for each data structure present. Give any 1 item from each list.

GAVISOL last/next (1,6)) 11 Gndf [1,2,3,4,5] print 2,3

Repetitive operations: [0] * 3 will print 3 times.

Accessing Elements. fruits = ["apple", "banana", "cherry", "date", "pineapple"]

	0	1	2	3	4
index					
neg index	-5	-4	-3	-2	-1

print(fruits[1]) // banana, print(fruits[-2]) // date

licing → fruits[2:4] // 2 to 4 index, 4 last index not include
fruits[:3] // 0-3 index.
fruits[3:] // 3 to last index.
fruits[0:4:2] // 0 to 4 index, 4 last index not include, 2 step
Ex: fruits[0:4:2] = 0, 2, 4 index, 4 last index not include, 2 step
fruits[:2] // 0 to 2 index, 2 last index not include
fruits[-1:-2] // -1 to -2 index, -2 last index not include
fruits[fruits[-1:-2]] // negative index print value + sign

Replacement value

fruits[0:3] = ["Mango", "Lichee", "Dragon"] // 0-2 index value replace
print(fruits) // value updated and assign again

fruits[1:1] = ["Mango", "Lichee", "Dragon"] // 1 index value replace
fruits[2:4] = [] // empty list, delete process, 2, 3 index delete
fruits[1] = ["Lichee"] // 1 index insert value, 2 index replacement
del fruits[0] // 0 index value delete; del fruits[1:3] // 1-2 index delete

Concatenation:

fruits1 = ["a", "b", "c", "d"], fruits2 = ["e", "f", "g"]
fruits = fruits1 + fruits2 = print(fruits) // ["a", "b", "c", "d", "e", "f", "g"]

append fruits.append("Mango") // last index value add
("Mango", "Banana") // possible 2 or more argument

extend fruits.extend(["Mango"]) // extend method use and, fruits.extend(["Mango", "Banana"])
("Mango", "Banana") // extend method use and, fruits.extend(["Mango", "Banana"])

fruits.insert(1, "Lichee") // 1 index value insert

Remove:

fruits.remove("apple") // apple remove and replace by next value

fruits.pop() // last index value delete and return value
fruits.pop(1) // 1 index value delete and return value
fruits.pop(-1) // last index value delete and return value

fruits.pop(2) // 2 index value delete and return value

fruits.clear() // list empty

fruits.sort() // sort alphabet and value // fruits.sort(reverse=True)

fruits.index() // index value, fruits.count("apple") // apple count

I #sum(), numbers=[0,1,2,3,4], sum(numbers).

#20 - class :

LIST comprehension: python 3 syntax for list

Squares = [] // Traditional Loop
 for x in range(5):
 squares.append(x**2)
 squares = [x**2 for x in range(5)]
 // range(5) after x=4 0, 1, 2, 3, 4
 // list comprehension

OR

num = [1, 2, 3, 4, 5]
 even = []
 for x in num:
 if x%2==0:
 even.append(x)
 print(even)
 numbers = [1, 2, 3, 4, 5]
 even = [x for x in num if x%2==0]
 // condition to append (even)
 // condition to append (even)

data structures.

Data structures: (5) 1) list 2) tuple 3) dictionary 4) set 5) queue 6) stack
 - the way of organizing & storing data so that it can be accessed & modified efficiently.
 List: (array) item container, fruits = ['apple', 'banana', 'mango'] [list mutable] [list can append & delete]
 Tuple: list of no change data, fruits = ('apple', 'banana', 'mango') [tuple immutable]
 Set: duplicate value storage, numbers = {1, 2, 3} [first bracket is set] [tuple can append but not delete]
 Dictionary: key, value pairs, student = {'name': 'Rishi', 'age': 20}
 List mutable, Tuple immutable
 list = [], tuple = ()
 first order data store, (order) data store
 duplicate allow, duplicates allow
 ordered, ordered (indexing possible) ordered, (index) set is unordered

Tuples are faster than list (as tuples can't be changed again), tuple for unique values.

Set: Unordered, Unique items (no duplicate), no index, remove, insert, index, order maintain, faster, arithmetic type.

Example: `my_set = {1, 2, 3}` // dictionary

Remove: `my_set.remove(1)` // error if not present

Set operations: `my_set.add(4)`, `my_set.update([5, 6])`, `my_set.discard(1)`, `my_set.pop()`, `my_set.clear()`.

Set difference: `A - B` // elements in A but not in B.

Set intersection: `A & B` // elements common to both A and B.

Set union: `A | B` // elements from both A and B.

Dictionary: ordered, changeable, syntax {key: value}.

Example: `student = {"name": "Aiko", "age": 22, "grade": "A"}`

Operations: `student.get("name")`, `student["name"]`, `student.pop("age")`, `student.clear()`.

Comparison:

	List	Tuple	Set	Dictionary
ordered	Yes	Yes	No	Yes (3.7+ version 2.5)
changeable	Yes	No	Yes	Yes
allow duplicate	Yes	Yes	No	No
Access	index	index	no index	key
empty	<code>[]</code>	<code>()</code>	<code>{}</code>	<code>{}</code>
Memory	Medium	Smallest	Largest	Largest

Keywords: `multiple positional arguments`, `multiple keyword arguments`.

GAVISOL

Ex: $(56, 2) = 56, (56, 0, 2) = 56, 0, (56, 6789, 2) = 56, 68$.
 Ex: $56, 2 = 56, 6789 = 56, 68, 56, 0 = 56, 00$.

→ 2nd step is to define a function. In 2nd [def square] is a named function.

[illegible]

Equivalent form: `def square(x): return x**2` // named fⁿ.

key word
 Map::move() - can insert list / array iterable as element as it is an iterable

Ex: square, lambda, 0, 1, max, sort

Ex, $arr = [1, 2, 3, 4, 5]$
 ... $if (i \leq arr.length - 1 \text{ and } arr[i] \neq 0, num)$ print $\#$ res $at [2, 4, 5]$.

sort: sorted(iterable, key=None/reversed, reverse=False) iterable: list/tuple/dictionary

Key: ২০০৫ সালের ১০/১১/০৫ সাল

sorted (words, key=len) // key=len call 2nd arg string len in ascending order

• texture map fill (text, 4) // Gr-string put 4 colored grass, 1st eq 3 then new line
